CONCLUSION

INTRODUCTION:

- Round Robin Scheduling is a pre-emptive scheduling algorithm used in operating systems for managing processes or tasks.
- It is designed to provide fair and equal allocation of CPU time among multiple processes.

BASIC CONCEPT:

- Each process is assigned a fixed time unit known as a time quantum or time slice.
- The scheduler cycles through the processes, allocating each one the CPU for its time quantum.
- Once a process's time quantum expires, it is preempted, and the CPU is allocated to the next process in the queue.

The background of the image features a series of thin, black, concentric curved lines that sweep across the frame from the top-left and bottom-left towards the right. These lines create a sense of depth and movement, resembling a stylized tunnel or a series of overlapping wavefronts. The lines are more densely packed on the left side and become more sparse as they move towards the right.

CODE EXPLANATION

ADVANTAGES:

- **Prevents Starvation**
- **Low Response Time for Short Tasks**
- **Simple Implementation**
- **Supports Time Sharing**
- **Dynamic Priority Adjustment**

CONCLUSION:

- In conclusion, Round Robin scheduling is a widely favored CPU scheduling algorithm for its simplicity, fairness, and predictable performance.
- Despite potential overhead from frequent context switching, its advantages in preventing starvation.
- Supporting time-sharing, and ensuring low response times for short tasks underscore its enduring relevance in diverse computing environments.

The background features a series of thin, black, concentric curved lines that sweep across the frame, creating a sense of motion and depth. These lines are centered around the text, which is placed in the middle of the composition.
